The Healing Brush is a replacement of the Clone Stamp that allows you to select an area of an image and remove the broken or corrupted pixels. The Spot Healing Brush is good for smaller errors, such as little dust particles or inconsistencies in the colors. The Pencil Tool is similar to a marker, with the added ability to allow you to paint on your images. The Dodge Tool allows you to change the tonal value of a photo, making it more interesting or more contrasty. The Burn Tool allows you to adjust the color of an image. It's good for making images brighter or darker. The Eraser tool allows you to erase pixels from your image. The Paint Bucket makes it easy to paint a selected area of an image. The Gradient Tool allows you to make a color transition in one area. You can use the tool to create a gradient, which is used often in graphic design. The Dodge and Burn Tools let you change the tone of selected areas of an image. The Smudge Tool allows you to blur an image, making it look more painterly. The Lens Blur Tool lets you add a "blur" to the image to create a watermark or more interesting image. The Clone Stamp Tool allows you to duplicate, copy, and paste pixels from one area to another. The Spot Healing Brush Tool allows you to select an area of an image that has lost one or more pixels. Q: Abstract factory vs builder pattern - when to use them? I am trying to use the builder pattern in my projects, but everytime I refactor I am wondering how to use them correctly. As far as I understand it, using the builder in the following scenario is wrong: You have a class that depends on another class. You have to create many instances of this class. You want to save space by storing data that does not need to be exposed as part of the public api. So, I would write a class that would build the object. I would use a factory for this, but the factory needs knowledge of what needs to be built. This is where I get confused. Why do we need to use the factory? Why do we need an object to encapsulate the data that is not required for the public api (e.g. the person)? Is it because of time saving? I feel like I am repeating myself. I don't know what to say to other developers. With regards to my second reason, do I simply need to define a factory interface for this class? Can the builder write to a database as the factory in the above scenario is doing? Is this even possible? With regards to the first reason, does it matter if the factory interface is being implemented in a separate class? Would the object need to be passed to the factory to instantiate? Would I need to pass any additional data into the factory? Also, I noticed a new pattern that is being used in many frameworks. Maybe it would help to clarify things for me. Instead of: var person = new PersonBuilder(19).WithName("John Doe").WithAge(50).WithPhoneNumber("097112345678"); It would be: var person = Person.CreateBuilder() .WithName("John Doe") .WithAge(50) .WithPhoneNumber("097112345678"); A: The problem is, that you are possibly repeating yourself. You have a class that depends on another class. Should be a constructor dependency, not a factory, or a factory with constructor dependencies. Using a factory to
